(54) **Polishing articles for electrochemical mechanical polishing of substrates**

(57) An article of manufacture, method, and apparatus are provided for planarizing a substrate surface. In one aspect, an article of manufacture is provided for polishing a substrate including a polishing article (205) having a body comprising at least a portion (310) of fibers coated with a conductive material, conductive fillers, or combinations thereof, and adapted to polish the substrate. In another aspect, a polishing article includes a body having a surface adapted to polish the substrate and at least one conductive element embedded in the polishing surface, the conductive element comprising dielectric or conductive fibers coated with a conductive material, conductive fillers, or combinations thereof. The conductive element may have a contact surface that extends beyond a plane defined by the polishing surface. A plurality of perforations (546) and a plurality of grooves (542) may be formed in the articles to facilitate flow of material through and around the polishing article.

*Fig. 5*

## Description

[0001] The present invention relates to an article of manufacture and apparatus for planarizing a substrate surface.

[0002] Sub-quarter micron multi-level metallization is one of the key technologies for the next generation of ultra large-scale integration (ULSI). The multilevel interconnects that lie at the heart of this technology require planarization of interconnect features formed in high aspect ratio apertures, including contacts, vias, lines and other features. Reliable formation of these interconnect features is very important to the success of ULSI and to the continued effort to increase circuit density and quality on individual substrates and die.

[0003] In the fabrication of integrated circuits and other electronic devices, multiple layers of conducting, semiconducting, and dielectric materials are deposited on or removed from a surface of a substrate. Thin layers of conducting, semiconducting, and dielectric materials may be deposited by a number of deposition techniques. Common deposition techniques in modern processing include physical vapor deposition (PVD), also known as sputtering, chemical vapor deposition (CVD), plasma-enhanced chemical vapor deposition (PECVD), and electro-chemical plating (ECP).

[0004] As layers of materials are sequentially deposited and removed, the uppermost surface of the substrate may become non-planar across its surface and require planarization. Planarizing a surface, or "polishing" a surface, is a process where material is removed from the surface of the substrate to form a generally even, planar surface. Planarization is useful in removing undesired surface topography and surface defects, such as rough surfaces, agglomerated materials, crystal lattice damage, scratches, and contaminated layers or materials. Planarization is also useful in forming features on a substrate by removing excess deposited material used to fill the features and to provide an even surface for subsequent levels of metallization and processing.

[0005] Chemical mechanical planarization, or chemical mechanical polishing (CMP), is a common technique used to planarize substrates. CMP utilizes a chemical composition, typically a slurry or other fluid medium, for selective removal of material from substrates. In conventional CMP techniques, a substrate carrier or polishing head is mounted on a carrier assembly and positioned in contact with a polishing pad in a CMP apparatus. The carrier assembly provides a controllable pressure to the substrate urging the substrate against the polishing pad. The pad is moved relative to the substrate by an external driving force. The CMP apparatus effects polishing or rubbing movement between the surface of the substrate and the polishing pad while dispersing a polishing composition to effect chemical activity and/or mechanical activity and consequential removal of material from the surface of the substrate.

[0006] One material increasingly utilized in integrated circuit fabrication is copper due to its desirable electrical properties. However, copper has its own special fabrication problems. For example, copper is difficult to pattern and etch and new processes and techniques, such as damascene or dual damascene processes, are being used to form copper substrate features.

[0007] In damascene processes, a feature is defined in a dielectric material and subsequently filled with copper. Dielectric materials with low dielectric constants, *i.e.*, less than about 3, are being used in the manufacture of copper damascenes. Barrier layer materials are deposited conformally on the surfaces of the features formed in the dielectric layer prior to deposition of copper material. Copper material is then deposited over the barrier layer and the surrounding field. However, copper fill of the features usually results in excess copper material, or overburden, on the substrate surface that must be removed to form a copper filled feature in the dielectric material and prepare the substrate surface for subsequent processing.

[0008] One challenge that is presented in polishing copper materials is that the interface between the conductive material and the barrier layer is generally non-planar and residual copper material is retained in irregularities formed by the non-planar interface. Further, the conductive material and the barrier materials are often removed from the substrate surface at different rates, both of which can result in excess conductive material being retained as residues on the substrate surface. Additionally, the substrate surface may have different surface topography, depending on the density or size of features formed therein. Copper material is removed at different removal rates along the different surface topography of the substrate surface, which makes effective removal of copper material from the substrate surface and final planarity of the substrate surface difficult to achieve.

[0009] One solution to remove all of the desired copper material from the substrate surface is to overpolish the substrate surface. However, overpolishing of some materials can result in the formation of topographical defects, such as concavities or depressions in features, referred to as dishing, or excessive removal of dielectric material, referred to as erosion. The topographical defects from dishing and erosion can further lead to non-uniform removal of additional materials, such as barrier layer materials disposed thereunder, and produce a substrate surface having a less than desirable polishing quality.

[0010] Another problem with the polishing of copper surfaces arises from the use of low dielectric constant (low *k*) dielectric materials to form copper damascenes in the substrate surface. Low *k* dielectric materials, such as carbon doped silicon oxides, may deform or fracture under conventional polishing pressures (*i.e.*, about 6 psi), called downforce, which can detrimentally affect substrate polish quality and detrimentally affect device

formation. For example, relative rotational movement between the substrate and a polishing pad can induce a shear force along the substrate surface and deform the low k material to form topographical defects, which can detrimentally affect subsequent polishing.

[0011] One solution for polishing copper in low dielectric materials is by polishing copper by electrochemical mechanical polishing (ECMP) techniques. ECMP techniques remove conductive material from a substrate surface by electrochemical dissolution while concurrently polishing the substrate with reduced mechanical abrasion compared to conventional CMP processes. The electrochemical dissolution is performed by applying a bias between a cathode and substrate surface to remove conductive materials from a substrate surface into a surrounding electrolyte.

[0012] In one embodiment of an ECMP system, the bias is applied by a ring of conductive contacts in electrical communication with the substrate surface in a substrate support device, such as a substrate carrier head. However, the contact ring has been observed to exhibit non-uniform distribution of current over the substrate surface, which results in non-uniform dissolution. Mechanical abrasion is performed by contacting the substrate with a conventional polishing pad and providing relative motion between the substrate and polishing pad. However, conventional polishing pads often limit electrolyte flow to the surface of the substrate. Additionally, the polishing pad may be composed of insulative materials that may interfere with the application of bias to the substrate surface and result in non-uniform or variable dissolution of material from the substrate surface.

[0013] As a result, there is a need for an improved polishing article for the removal of conductive material on a substrate surface.

[0014] Aspects of the invention generally provide an article of manufacture and an apparatus for planarizing a layer on a substrate using electrochemical deposition techniques, electrochemical dissolution techniques, polishing techniques, and/or combinations thereof.

[0015] In one aspect, a polishing article for polishing a substrate includes a body having a surface adapted to polish the substrate and at least one conductive element embedded at least partially in the body. The conductive element may include fibers coated with a conductive material, a conductive filler, or combinations thereof, which may be disposed in a binder material. The conductive element may include a fabric of interwoven fibers coated with the conductive material embedded at least partially in the body, a composite of fibers coated with the conductive material, conductive fillers, or combinations thereof, and a binder, embedded at least partially in the body, or combinations thereof. The conductive element may have a contact surface that extends beyond a plane defined by the polishing surface and may comprise a coil, one or more loops, one or more strands, an interwoven fabric of materials, or combinations thereof. A plurality of perforations and a plurality

of grooves may be formed in the polishing article to facilitate flow of material through and across the polishing article.

[0016] In another aspect, a polishing article is provided for processing a substrate surface, such as a conductive layer deposited on the substrate surface. The polishing article include a body comprising at least a portion of conductive fillers, fibers coated with a conductive material, or combinations thereof, and adapted to polish the substrate. A plurality of perforations and a plurality of grooves may be formed in the polishing article to facilitate flow of material through and around the polishing article.

[0017] In another aspect, the polishing articles may be disposed in an apparatus for processing a substrate including a basin, a permeable disc disposed in the basin, the polishing article or the article of manufacture disposed on the permeable disk, an electrode disposed in the basin between the permeable disc and the bottom of the basin, and a polishing head adapted to retain the substrate during processing.

[0018] In another aspect, the polishing articles may be used as a conductive polishing article in a method for processing a substrate including providing an apparatus containing an enclosure, disposing a conductive polishing article in the enclosure, supplying an electrically conductive solution to the enclosure at a flow rate up to about 20 gallons per minute (GPM), positioning the substrate adjacent the conductive polishing article in the electrically conductive solution, contacting a surface of the substrate with the conductive polishing article in the electrically conductive solution, applying a bias between an electrode and the conductive polishing article, and removing at least a portion of the surface of the substrate surface.

[0019] In another aspect, a polishing article is provided for processing a substrate, including a body having at least a conductive surface adapted to polish the substrate, wherein the conductive surface comprises at least one conductive element comprising conductive fillers, fibers coated with a conductive material, or combinations thereof, disposed in a polymeric material.

[0020] In another aspect, a polishing article is provided for processing a substrate, including a body having a surface adapted to polish the substrate and a conductive element comprising a fabric of interwoven fibers coated with a conductive material.

[0021] So that the manner in which the above recited aspects of the invention are attained and can be understood in detail, a more particular description of the invention, briefly summarized above, may be had by reference to embodiments thereof which are illustrated in the appended drawings.

[0022] It is to be noted, however, that the appended drawings illustrate only typical embodiments of this invention and, therefore, are not to be considered limiting of its scope, for the invention may admit to other equally effective embodiments.

[0044] The words and phrases used herein should be given their ordinary and customary meaning in the art by one skilled in the art unless otherwise further defined. Chemical-mechanical polishing should be broadly construed and includes, but is not limited to, abrading a substrate surface by chemical activity, mechanical activity, or a combination of both chemical and mechanical ac-

tivity. Electropolishing should be broadly construed and includes, but is not limited to, planarizing a substrate by the application of electrochemical activity, such as by anodic dissolution.

[0045] Electrochemical mechanical polishing (ECMP) should be broadly construed and includes, but is not limited to, planarizing a substrate by the application of electrochemical activity, chemical activity, mechanical activity, or a combination of electrochemical, chemical, and mechanical activity to remove material from a substrate surface.

[0046] Electrochemical mechanical plating process (ECMPP) should be broadly construed and includes, but is not limited to, electrochemically depositing material on a substrate and generally planarizing the deposited material by the application of electrochemical activity, chemical activity, mechanical activity, or a combination of electrochemical, chemical, and mechanical activity.

[0047] Anodic dissolution should be broadly construed and includes, but is not limited to, the application of an anodic bias to a substrate directly or indirectly which results in the removal of conductive material from a substrate surface and into a surrounding electrolyte solution. Polishing surface is broadly defined as the portion of an article of manufacture that at least partially contacts a substrate surface during processing or electrically couples an article of manufacture to a substrate surface either directly through contact or indirectly through an electrically conductive medium.

#### Polishing Apparatus

[0048] Figure 1 depicts a processing apparatus 100 having at least one station suitable for electrochemical deposition and chemical mechanical polishing, such as electrochemical mechanical polishing (ECMP) station 102 and at least one conventional polishing or buffing station 106 disposed on a single platform or tool. One polishing tool that may be adapted to benefit from the invention is a MIRRA® Mesa™ chemical mechanical polisher available from Applied Materials, Inc. located in Santa Clara, California.

[0049] For example, in the apparatus 100 shown in Figure 1, the apparatus 100 includes two ECMP stations 102 and one polishing station 106. The stations may be used for processing a substrate surface. For example, a substrate having feature definitions formed therein and filled with a barrier layer and then a conductive material disposed over the barrier layer may have the conductive material removed in two steps in the two ECMP stations 102 with the barrier layer polished in the polishing station 106 to form a planarized surface.

[0050] The exemplary apparatus 100 generally includes a base 108 that supports one or more ECMP stations 102, one or more polishing stations 106, a transfer station 110 and a carousel 112. The transfer station 110 generally facilitates transfer of substrates 114 to and from the apparatus 100 via a loading robot 116. The

loading robot 116 typically transfers substrates 114 between the transfer station 110 and a factory interface 120 that may include a cleaning module 122, a metrology device 104 and one or more substrate storage cassettes 118. One example of a metrology device 104 is a NovaScan™ Integrated Thickness Monitoring system, available from Nova Measuring Instruments, Inc., located in Phoenix, Arizona.

[0051] Alternatively, the loading robot 116 (or factory interface 120) may transfer substrates to one or more other processing tools (not shown) such as a chemical vapor deposition tool, physical vapor deposition tool, etch tool and the like.

[0052] In one embodiment, the transfer station 110 comprises at least an input buffer station 124, an output buffer station 126, a transfer robot 132, and a load cup assembly 128. The loading robot 116 places the substrate 114 onto the input buffer station 124. The transfer robot 132 has two gripper assemblies, each having pneumatic gripper fingers that hold the substrate 114 by the substrate's edge. The transfer robot 132 lifts the substrate 114 from the input buffer station 124 and rotates the gripper and substrate 114 to position the substrate 114 over the load cup assembly 128, then places the substrate 114 down onto the load cup assembly 128.

[0053] The carousel 112 generally supports a plurality of polishing heads 130, each of which retains one substrate 114 during processing. The carousel 112 transfers the polishing heads 130 between the transfer station 110, the one or more ECMP stations 102 and the one or more polishing stations 106. One carousel 112 that may be adapted to benefit from the invention is generally described in United States Patent No. 5,804,507, issued September 8, 1998 to Tolles et al., which is hereby incorporated by reference to the extent it is not inconsistent with the claims and disclosure herein.

[0054] Generally, the carousel 112 is centrally disposed on the base 108. The carousel 112 typically includes a plurality of arms 138. Each arm 138 generally supports one of the polishing heads 130. One of the arms 138 depicted in Figure 1 is not shown so that the transfer station 110 may be seen. The carousel 112 is indexable such that the polishing head 130 may be moved between the stations 102, 106 and the transfer station 110 in a sequence defined by the user.

[0055] Generally the polishing head 130 retains the substrate 114 while the substrate 114 is disposed in the ECMP station 102 or polishing station 106. The arrangement of the ECMP stations 106 and polishing stations 102 on the apparatus 100 allow for the substrate 114 to be sequentially plated or polished by moving the substrate between stations while being retained in the same polishing head 130. One polishing head that may be adapted to the invention is a TITAN HEAD™ substrate carrier, manufactured by Applied Materials, Inc., located in Santa Clara, California.

[0056] Examples of embodiments of polishing heads 130 that may be used with the polishing apparatus 100

described herein are described in United States Patent No. 6,024,630, issued February 25, 2000 to Shendon, et al., which is hereby incorporated by reference to the extent it is not inconsistent with the claims and disclosure herein.

[0057] To facilitate control of the polishing apparatus 100 and processes performed thereon, a controller 140 comprising a central processing unit (CPU) 142, memory 144, and support circuits 146, is connected to the polishing apparatus 100. The CPU 142 may be one of any form of computer processor that can be used in an industrial setting for controlling various drives and pressures. The memory 144 is connected to the CPU 142. The memory 144, or computer-readable medium, may be one or more of readily available memory such as random access memory (RAM), read only memory (ROM), floppy disk, hard disk, or any other form of digital storage, local or remote. The support circuits 146 are connected to the CPU 142 for supporting the processor in a conventional manner. These circuits include cache, power supplies, clock circuits, input/output circuitry, subsystems, and the like.

[0058] Power to operate the polishing apparatus 100 and/or the controller 140 is provided by a power supply 150. Illustratively, the power supply 150 is shown connected to multiple components of the polishing apparatus 100, including the transfer station 110, the factory interface 120, the loading robot 116 and the controller 140. In other embodiments separate power supplies are provided for two or more components of the polishing apparatus 100.

[0059] Figure 2 depicts a sectional view of the polishing head 130 supported above an ECMP station 102. The ECMP station 102 generally includes a basin 202, an electrode 204, polishing article 205, a disc 206 and a cover 208. In one embodiment, the basin 202 is coupled to the base 108 of the polishing apparatus 100. The basin 202 generally defines a container or electrolyte cell in which a conductive fluid such as an electrolyte 220 can be confined. The electrolyte 220 used in processing the substrate 114 can be used to process metals such as copper, aluminum, tungsten, gold, silver, or any other materials that can be electrochemically deposited onto or electrochemically removed from the substrate 114.

[0060] The basin 202 can be a bowl shaped member made of a plastic such as fluoropolymers, TEFLON®, PFA, PE, PES, or other materials that are compatible with electroplating and electropolishing chemistries. The basin 202 has a bottom 210 that includes an aperture 216 and a drain 214. The aperture 216 is generally disposed in the center of the bottom 210 and allows a shaft 212 to pass therethrough. A seal 218 is disposed between the aperture 216 and the shaft 212 and allows the shaft 212 to rotate while preventing fluids disposed in the basin 202 from passing through the aperture 216.

[0061] The basin 202 typically includes the electrode 204, the disc 206, and the polishing article 205 disposed

therein. Polishing article 205, such as a polishing pad, is disposed and supported in the basin 202 on the disc 206.

**[0062]** The electrode 204 is a counter-electrode to the substrate 114 and/or polishing article 205 contacting a substrate surface. The polishing article 205 is at least partially conductive and may act as an electrode in combination with the substrate during electrochemical processes, such as an electrochemical mechanical plating process (ECMPP), which includes electrochemical deposition and chemical mechanical polishing, or electrochemical dissolution. The electrode 204 may be an anode or cathode depending upon the positive bias (anode) or negative bias (cathode) applied between the electrode 204 and polishing article 405.

**[0063]** For example, depositing material from an electrolyte on the substrate surface, the electrode 204 acts as an anode and the substrate surface and/or polishing article 205 acts as a cathode. When removing material from a substrate surface, such as by dissolution from an applied bias, the electrode 204 functions as a cathode and the substrate surface and/or polishing article 205 may act as an anode for the dissolution process.

**[0064]** The electrode 204 is generally positioned between the disc 206 and the bottom 210 of the basin 202 where it may be immersed in the electrolyte 220. The electrode 204 can be a plate-like member, a plate having multiple apertures formed therethrough, or a plurality of electrode pieces disposed in a permeable membrane or container. A permeable membrane (not shown) may be disposed between the disc 206 and the electrode 204 or electrode 204 and polishing article 205 to filter bubbles, such as hydrogen bubbles, from the wafer surface and to reduce defect formation and stabilize or more uniformly apply current or power therebetween.

**[0065]** For electrodeposition processes, the electrode 204 is made of the material to be deposited or removed, such as copper, aluminum, gold, silver, tungsten and other materials which can be electrochemically deposited on the substrate 114. For electrochemical removal processes, such as anodic dissolution, the electrode 204 may include a non-consumable electrode of a material other than the deposited material, for example, platinum, carbon, or aluminum, for copper dissolution.

**[0066]** The polishing article 205 can be a pad, a web or a belt of material, which is compatible with the fluid environment and the processing specifications. In the embodiment depicted in Figure 2, the polishing article 205 is circular in form and positioned at an upper end of the basin 202, supported on its lower surface by the disc 206. The polishing article 205 includes at least a partially conductive surface of a conductive material, such as one or more conductive elements, for contact with the substrate surface during processing. The polishing article 205 may be a portion or all of a conductive polishing material or a composite of a conductive polishing material embedded in or disposed on a conventional polishing material. For example the conductive material may

be disposed on a "backing" material disposed between the disc 206 and polishing article 205 to tailor the compliance and/or durometer of the polishing article 205 during processing.

**[0067]** The basin 202, the cover 208, and the disc 206 may be movably disposed on the base 108. The basin 202, cover 208 and disc 206 may be axially moved toward the base 108 to facilitate clearance of the polishing head 130 as the carousel 112 indexes the substrate 114 between the ECMP and polishing stations 102, 106. The disc 206 is disposed in the basin 202 and coupled to the shaft 212. The shaft 212 is generally coupled to a motor 224 disposed below the base 108. The motor 224, in response to a signal from the controller 140, rotates the disc 206 at a predetermined rate.

**[0068]** The disc 206 may be a perforated article support made from a material compatible with the electrolyte 220 which would not detrimentally affect polishing. The disc 206 may be fabricated from a polymer, for example fluoropolymers, PE, TEFLON®, PFA, PES, HDPE, UHMW or the like. The disc 206 can be secured in the basin 202 using fasteners such as screws or other means such as snap or interference fit with the enclosure, being suspended therein and the like. The disc 206 is preferably spaced from the electrode 204 to provide a wider process window, thus reducing the sensitivity of depositing material and removing material from the substrate surface to the electrode 204 dimensions.

**[0069]** The disc 206 is generally permeable to the electrolyte 220. In one embodiment, the disc 206 includes a plurality of perforations or channels 222 formed therein. Perforations include apertures, holes, openings, or passages formed partially or completely through an object, such as the polishing article. The perforation size and density is selected to provide uniform distribution of the electrolyte 220 through the disc 206 to the substrate 114.

**[0070]** In one aspect of the disc 206 includes perforations having a diameter between about 0.02 inches (0.5 millimeters) and about 0.4 inches (10 mm). The perforations may have a perforation density between about 20% and about 80% of the polishing article. A perforation density of about 50% has been observed to provide electrolyte flow with minimal detrimental effects to polishing processes. Generally, the perforations of the disc 206 and the polishing article 205 are aligned to provide to provide for sufficient mass flow of electrolyte through the disc 206 and polishing article 205 to the substrate surface. The polishing article 205 may be disposed on the disc 206 by a mechanical clamp or conductive adhesive.

**[0071]** While the polishing articles described herein for electrochemical-mechanical polishing (ECMP) processes, the invention contemplates using the conductive polishing article in other fabrication processes involving electrochemical activity. Examples of such processes using electrochemical activity include electrochemical deposition, which involves the polishing article 205 be-

ing used to apply an uniform bias to a substrate surface for depositing a conductive material without the use of conventional bias application apparatus, such as edge contacts, and electrochemical mechanical plating processes (ECMPP) that include a combination of electrochemical deposition and chemical mechanical polishing.

**[0072]** In operation, the polishing article 205 is disposed on the disc 206 in an electrolyte in the basin 202. A substrate 114 on the polishing head is disposed in the electrolyte and contacted with the polishing article 205. Electrolyte is flowed through the perforations of the disc 206 and the polishing article 205 and is distributed on the substrate surface by grooves formed therein. Power from a power source is then applied to the conductive polishing article 205 and the electrode 204, and conductive material, such as copper, in the electrolyte is then removed by an anodic dissolution method.

**[0073]** The electrolyte 220 is flowed from a reservoir 233 into the volume 232 via a nozzle 270. The electrolyte 220 is prevented from overflowing the volume 232 by a plurality of holes 234 disposed in a skirt 254. The holes 234 generally provide a path through the cover 208 for the electrolyte 220 exiting the volume 232 and flowing into the lower portion of the basin 202. At least a portion of the holes 234 are generally positioned between a lower surface 236 of the depression 258 and the center portion 252. As the holes 234 are typically higher than the lower surface 236 of the depression 258, the electrolyte 220 fills the volume 232 and is thus brought into contact with the substrate 214 and polishing medium 205. Thus, the substrate 214 maintains contact with the electrolyte 220 through the complete range of relative spacing between the cover 208 and the disc 206.

**[0074]** The electrolyte 220 collected in the basin 202 generally flows through the drain 214 disposed at the bottom 210 into the fluid delivery system 272. The fluid delivery system 272 typically includes the reservoir 233 and a pump 242. The electrolyte 220 flowing into the fluid delivery system 272 is collected in the reservoir 233. The pump 242 transfers the electrolyte 220 from the reservoir 233 through a supply line 244 to the nozzle 270 where the electrolyte 220 recycled through the ECM station 102. A filter 240 is generally disposed between the reservoir 233 and the nozzle 270 to remove particles and agglomerated material that may be present in the electrolyte 220.

**[0075]** Electrolyte solutions may include commercially available electrolytes. For example, in copper containing material removal, the electrolyte may include sulfuric acid based electrolytes or phosphoric acid based electrolytes, such as potassium phosphate ( $K_3PO_4$ ), or combinations thereof. The electrolyte may also contain derivatives of sulfuric acid based electrolytes, such as copper sulfate, and derivatives of phosphoric acid based electrolytes, such as copper phosphate. Electrolytes having perchloric acid-acetic acid solutions and deriva-

tives thereof may also be used.

**[0076]** Additionally, the invention contemplates using electrolyte compositions conventionally used in electroplating or electropolishing processes, including conventionally used electroplating or electropolishing additives, such as brighteners among others. One source for electrolyte solutions used for electrochemical processes such as copper plating, copper anodic dissolution, or combinations thereof is Shipley Leonel, a division of Rohm and Haas, headquartered in Philadelphia, Pennsylvania, under the tradename Ultrafill 2000. An example of a suitable electrolyte composition is described in United States Patent Application Serial No. 10/038,066, filed on January 3, 2002, which is incorporated by reference to the extent not inconsistent with the aspects and claims herein.

**[0077]** Electrolyte solutions are provided to the electrochemical cell to provide a dynamic flow rate on the substrate surface or between the substrate surface and an electrode at a flow rate up to about 20 gallons per minute (GPM), such as between about 0.5 GPM and about 20 GPM, for example, at about 2 GPM. It is believed that such flow rates of electrolyte evacuate polishing material and chemical by-products from the substrate surface and allow refreshing of electrolyte material for improved polishing rates.

**[0078]** When using mechanical abrasion in the polishing process, the substrate 114 and polishing article 205 are rotated relative to one another to remove material from the substrate surface. Mechanical abrasion may be provided by physical contact with both conductive polishing materials and conventional polishing materials as described herein. The substrate 114 and the polishing article 205 are respectively rotated at about 5 rpms or greater, such as between about 10 rpms and about 50 rpms.

**[0079]** In one embodiment, a high rotational speed polishing process may be used. The high rotational speed process includes rotating the polishing article 205 at a platen speed of about 150 rpm or greater, such as between about 150 rpm and about 750 rpm; and the substrate 114 may be rotated at a rotational speed between about 150 rpm and about 500 rpm, such as between about 300 rpm and about 500 rpm. Further description of a high rotational speed polishing process that may be used with the polishing articles, processes, and apparatus described herein is disclosed in U.S. Patent Application Serial No. 60/308,030, filed on 7/25/2001, and entitled, "Method And Apparatus For Chemical Mechanical Polishing Of Semiconductor Substrates." Other motion, including orbital motion or a sweeping motion across the substrate surface, may also be performed during the process.

**[0080]** When contacting the substrate surface, a pressure of about 6 psi or less, such as about 2 psi or less is applied between the polishing article 205 and the substrate surface. A pressure between of about 2 psi or less, such as about 0.5 psi or less is used with substrate

containing low dielectric constant material between the substrate 114 and the polishing article 205 during polishing of the substrate. In one aspect, a pressure between about 0.1 psi and about 0.2 psi may be used to polishing substrates with conductive polishing articles as described herein.

**[0081]** In anodic dissolution, a potential difference or bias is applied between the electrode 204, performing as a cathode, and the polishing surface 310 of the polishing article 205, performing as the anode. The substrate in contact with the polishing article is polarized via the conductive polishing surface article 310 at the same time the bias is applied to the conductive article support member. The application of the bias allows removal of conductive material, such as copper-containing materials, formed on a substrate surface. Establishing the bias may include the application of a voltage of about 15 volts or less to the substrate surface. A voltage between about 0.1 volts and about 10 volts may be used to dissolve copper-containing material from the substrate surface and into the electrolyte. The bias may also produce a current density between about 0.1 milliamperes/cm<sup>2</sup> and about 50 milliamperes/cm<sup>2</sup>, or between about 0.1 amps to about 20 amps for a 200 mm substrate.

**[0082]** The signal provided by the power supply 150 to establish the potential difference and perform the anodic dissolution process may be varied depending upon the requirements for removing material from the substrate surface. For example, a time varying anodic signal may be provided to the conductive polishing medium 205. The signal may also be applied by electrical pulse modulation techniques. The electrical pulse modification technique comprises applying a constant current density or voltage over the substrate for a first time period, then applying a constant reverse voltage over the substrate for a second time period, and repeating the first and second steps. For example, the electrical pulse modification technique may use a varying potential from between about -0.1 volts and about -15 volts to between about 0.1 volts and about 15 volts.

**[0083]** With the correct perforation pattern and density on the polishing media, it is believed that biasing the substrate from the polishing article 205 provides uniform dissolution of conductive materials, such as metals, into the electrolyte from the substrate surface as compared to the higher edge removal rate and lower center removal rate from conventional edge contact-pins bias.

**[0084]** Conductive material, such as copper containing material can be removed from at least a portion of the substrate surface at a rate of about 15,000 Å/min or less, such as between about 100 Å/min and about 15,000 Å/min. In one embodiment of the invention where the copper material to be removed is about 12,000 Å thick, the voltage may be applied to the conductive polishing article 205 to provide a removal rate between about 100 Å/min and about 8,000 Å/min.

**[0085]** Following the electropolishing process, the substrate may be further polished or buffed to remove

barrier layer materials, remove surface defects from dielectric materials, or improve planarity of the polishing process using the conductive polishing article. An example of a suitable buffing process and composition is disclosed in co-pending U.S. Patent Application Serial No. 09/569,968, filed on May 11, 2000, and incorporated herein by reference to the extent not inconsistent with the claimed aspects or disclosure herein.

## 10 Polishing Article Materials

**[0086]** The polishing articles described herein may be formed from conductive materials that may comprise a conductive polishing material or may comprise a conductive element disposed in a dielectric or conductive polishing material. In one embodiment, a conductive polishing material may include conductive fibers, conductive fillers, or combinations thereof. The conductive fibers, conductive fillers, or combinations thereof may be dispersed in a polymeric material.

**[0087]** The conductive fibers may comprise conductive or dielectric materials, such as dielectric or conductive polymers or carbon-based materials, at least partially coated or covered with a conductive material including a metal, a carbon-based material, a conductive ceramic material, a conductive alloy, or combinations thereof. The conductive fibers may be in the form of fibers or filaments, a conductive fabric or cloth, one or more loops, coils, or rings of conductive fibers. Multiple layers of conductive materials, for example, multiple layers of conductive cloth or fabric, may be used to form the conductive polishing material.

**[0088]** The conductive fibers include dielectric or conductive fiber materials coated with a conductive material. Dielectric polymeric materials may be used as fiber materials. Examples of suitable dielectric fiber materials include polymeric materials, such as polyamides, polyimides, nylon polymer, polyurethane, polyester, polypropylene, polyethylene, polystyrene, polycarbonate, diene containing polymers, such as AES (polyacrylonitrile ethylene styrene), acrylic polymers, or combinations thereof.

**[0089]** The conductive fiber material may comprise intrinsically conductive polymeric materials including polyacetylene, polyethylenedioxythiophene (PEDT), which is commercially available under the trade name Baytron™, polyaniline, polypyrrole, polythiophene, carbon-based fibers, or combinations thereof. Another example of a conductive polymer is polymer-noble metal hybrid materials. Polymer-noble metal hybrid materials are generally chemically inert with a surrounding electrolyte, such as those with noble metals that are resistant to oxidation. An example of a polymer-noble metal hybrid material is a platinum-polymer hybrid material. Examples of conductive polishing materials, including conductive fibers, are more fully described in co-pending U.S. Patent Application Serial No. 10/033,732, filed on December 27, 2001, entitled, "Conductive Polishing

Article For Electrochemical Mechanical Polishing", which is incorporated herein by reference to the extent not inconsistent with the claimed aspects and description herein. The invention also contemplates the use of organic or inorganic materials that may be used as fibers described herein.

[0090] The fiber material may be solid or hollow in nature. The fiber length is in the range between about 1  $\mu\text{m}$  and about 1000 mm with a diameter between about 0.1  $\mu\text{m}$  and about 1 mm. In one aspect, the diameter of fiber may be between about 5  $\mu\text{m}$  to about 200  $\mu\text{m}$  with an aspect ratio of length to diameter of about 5 or greater, such as about 10 or greater, for conductive polymer composites and foams, such as conductive fibers disposed in polyurethane. The cross-sectional area of the fiber may be circular, elliptical, star-patterned, "snow flaked", or of any other shape of manufactured dielectric or conductive fibers. High aspect ratio fibers having a length between about 5 mm and about 1000 mm in length and between about 5  $\mu\text{m}$  and about 1000  $\mu\text{m}$  in diameter may be used for forming meshes, loops, fabrics or cloths, of the conductive fibers. The fibers may also have an elasticity modulus in the range between about  $10^4$  psi and about  $10^8$  psi. However, the invention contemplates any elastic modulus necessary to provide for compliant, elastic fibers in the polishing articles and processes described herein.

[0091] Conductive material disposed on the conductive or dielectric fiber material generally include conductive inorganic compounds, such as a metals metal, a carbon-based material, a conductive ceramic material, a metal inorganic compound, or combinations thereof. Examples of metal that may be used for the conductive material coatings herein include noble metals, copper, nickel, cobalt, and combinations thereof. Noble metals include gold, platinum, palladium, iridium, rhenium, rhodium, ruthenium, osmium, and combinations thereof, of which gold and platinum are preferred. The invention also contemplates the use of other metals for the conductive material coatings than those illustrated herein. Carbon-based material includes carbon black, graphite, and carbon particles capable of being affixed to the fiber surface. Examples of ceramic materials include niobium carbide (NbC), zirconium carbide (ZrC), tantalum carbide (TaC), titanium carbide (TiC), tungsten carbide (WC), and combinations thereof. The invention also contemplates the use of other metals, other carbon-based materials, and other ceramic materials for the conductive material coatings than those illustrated herein.

[0092] Metal inorganic compounds include, for example, copper sulfide or danjenite,  $\text{Cu}_9\text{S}_5$ , disposed on polymeric fibers, such as acrylic or nylon fibers. The danjenite coated fibers are commercially available under the tradename Thunderon® from Nihon Sanmo Dyeing Co., Ltd, of Japan. The Thunderon® fibers typically have a coating of danjenite,  $\text{Cu}_9\text{S}_5$ , between about 0.03  $\mu\text{m}$  and about 0.1  $\mu\text{m}$  and have been observed to have con-

ductivities of about 40  $\Omega/\text{cm}$ .

[0093] The conductive coating may be disposed directly on the fiber by plating, coating, physical vapor deposition, chemical deposition, binding, or bonding of the conductive materials. Additionally, a nucleation, or seed, layer of a conductive material, for example, copper, cobalt or nickel, may be used to improve adhesion between the conductive material and the fiber material. The conductive material may be disposed on individual dielectric or conductive fibers of variable lengths as well as on shaped loops, foams, and cloths or fabrics made out of the dielectric or conductive fiber material.

[0094] An example of a suitable conductive fiber is a polyethylene fiber coated with gold. Additional examples of the conductive fibers include acrylic fibers plated with gold and nylon fibers coated with rhodium. An example of a conductive fiber using a nucleation material is a nylon fiber coated with a copper seed layer and a gold layer disposed on the copper layer.

[0095] The conductive fillers may include carbon based materials or conductive particles and fibers. Examples of conductive carbon-based materials include carbon powder, carbon fibers, carbon nanotubes, carbon nanofoam, carbon aerogels, graphite, and combinations thereof. Examples of conductive particles or fibers include intrinsically conductive polymers, dielectric or conductive particles coated with a conductive material, dielectric filler materials coated in conductive materials, conductive inorganic particles, conductive ceramic particle, and combinations thereof. The conductive fillers may be partially or completely coated with a metal, such as a noble metal, a carbon-based material, conductive ceramic material, a metal inorganic compound, or combinations thereof, as described herein. An example of a filler material is a carbon fiber or graphite coated with copper or nickel. Conductive fillers may be spherical, elliptical, longitudinal with certain aspect ratio, such as 2 or greater, or of any other shape of manufactured fillers. Filler materials are broadly defined herein as materials that may be disposed in a second material to alter, the physical, chemical, or electrical properties of the second material. As such, filler materials may also include dielectric or conductive fiber material partially or completely coated in a conductive metal or conductive polymers as described herein. The fillers of dielectric or conductive fiber material partially or completely coated in a conductive metal or conductive polymers may also be complete fibers or pieces of fibers.

[0096] The conductive materials are used to coat both dielectric and conductive fibers and fillers to provide a desired level of conductivity for forming the conductive polishing material. Generally, the coating of conductive material is deposited on the fiber and/or filler material to a thickness between about 0.01  $\mu\text{m}$  and about 50  $\mu\text{m}$ , such as between about 0.02  $\mu\text{m}$  and about 10  $\mu\text{m}$ . The coating typically results in fibers or fillers having resistivities less than about 100  $\Omega\text{-cm}$ , such as between about 0.001  $\Omega\text{-cm}$  and about 32  $\Omega\text{-cm}$ . The invention

contemplates that resistivities are dependent on the materials of both the fiber or filler and the coating used, and may exhibit resistivities of the conductive material coating, for example, platinum, which has a resistivity 9.81  $\mu\Omega\text{-cm}$  at 0°C. An example of a suitable conductive fiber includes a nylon fiber coated with about 0.1  $\mu\text{m}$  copper, nickel, or cobalt, and about 2  $\mu\text{m}$  of gold disposed on the copper, nickel, or cobalt layer, with a total diameter of the fiber between about 30  $\mu\text{m}$  and about 90  $\mu\text{m}$ .

**[0097]** The conductive polishing material may include a combination of the conductive or dielectric fibers material at least partially coated or covered with an additional conductive material and conductive fillers for achieving a desired electrical conductivity or other polishing article properties. An example of a combination is the used of graphite and gold coated nylon fibers as the conductive material comprising at least a portion of a conductive polishing material.

**[0098]** The conductive fiber material, the conductive filler material, or combinations thereof, may be dispersed in a binder material or form a composite conductive polishing material. One form of binder material is a conventional polishing material. Conventional polishing materials are generally dielectric materials such as dielectric polymeric materials. Examples of dielectric polymeric polishing materials include polyurethane and polyurethane mixed with fillers, polycarbonate, polyphenylene sulfide (PPS), Teflon™ polymers, polystyrene, ethylene-propylene-diene-methylene (EPDM), or combinations thereof, and other polishing materials used in polishing substrate surfaces. The conventional polishing material may also include felt fibers impregnated in urethane or be in a foamed state. The invention contemplates that any conventional polishing material may be used as a binder material with the conductive fibers and fillers described herein.

**[0099]** Additives may be added to the binder material to assist the dispersion of conductive fibers, conductive fillers or combinations thereof, in the polymer materials. Additives may be used to improve the mechanical, thermal, and electrical properties of the polishing material formed from the fibers and/or fillers and the binder material. Additives include cross-linkers for improving polymer cross-linking and dispersants for dispersing conductive fibers or conductive fillers more uniformly in the binder material. Examples of cross-linkers include amino compounds, silane crosslinkers, polyisocyanate compounds, and combinations thereof. Examples of dispersants include N-substituted long-chain alkenyl succinimides, amine salts of high-molecular-weight organic acids, co-polymers of methacrylic or acrylic acid derivatives containing polar groups such as amines, amides, imines, imides, hydroxyl, ether, Ethylene-propylene copolymers containing polar groups such as amines, amides, imines, imides, hydroxyl, ether. In addition sulfur containing compounds, such as thioglycolic acid and related esters have been observed as effective dispersers for gold coated fibers and fillers in binder ma-

terials. The invention contemplates that the amount and types of additives will vary for the fiber or filler material as well as the binder material used, and the above examples are illustrative and should not be construed or interpreted as limiting the scope of the invention.

**[0100]** Further, a mesh of the conductive fiber and/or filler material may be formed in the binder material by providing sufficient amounts of conductive fiber and/or conductive filler material to form a physically continuous or electrically continuous medium or phase in the binder material. The conductive fibers and/or conductive fillers generally comprise between about 2 wt.% and about 85 wt.%, such as between about 5 wt.% and about 60 wt.%, of the polishing material when combined with a polymeric binder material.

**[0101]** An interwoven fabric or cloth of the fiber material coated with a conductive material, and optionally, a conductive filler, may be disposed in the binder. The fiber material coated with a conductive material may be interwoven to form a yarn. The yarns may be pressed together to make a conductive mesh with the help of adhesives or coatings. The yarn may be disposed as a conductive element in a polishing pad material or may be woven into a cloth or fabric.

**[0102]** Alternatively, the conductive fibers and/or fillers may be combined with a bonding agent to form a composite conductive polishing material. Examples of suitable bonding agents include epoxies, silicones, urethanes, polyimides, a polyamide, a fluoropolymer, fluorinated derivatives thereof, or combinations thereof. Additional conductive material, such as conductive polymers, additional conductive fillers, or combinations thereof, may be used with the bonding agent for achieving desired electrical conductivity or other polishing article properties. The conductive fibers and/or fillers may include between about 2 wt.% and about 85 wt.%, such as between about 5 wt.% and about 60 wt.%, of the composite conductive polishing material.

**[0103]** The conductive fiber and/or filler material may be used to form conductive polishing materials or articles having bulk or surface resistivity of about 50  $\Omega\text{-cm}$  or less, such as a resistivity of about 3  $\Omega\text{-cm}$  or less. In one aspect of the polishing article, the polishing article or polishing surface of the polishing article has a resistivity of about 1  $\Omega\text{-cm}$  or less. Generally, the conductive polishing material or the composite of the conductive polishing material and conventional polishing material are provided to produce a conductive polishing article having a bulk resistivity or a bulk surface resistivity of about 50  $\Omega\text{-cm}$  or less. An example of a composite of the conductive polishing material and conventional polishing material includes gold or carbon coated fibers which exhibit resistivities of 1  $\Omega\text{-cm}$  or less, disposed in a conventional polishing material of polyurethane in sufficient amounts to provide a polishing article having a bulk resistivity of about 10  $\Omega\text{-cm}$  or less.

**[0104]** The conductive polishing materials formed from the conductive fibers and/or fillers described herein

generally have mechanical properties that do not degrade under sustained electric fields and are resistant to degradation in acidic or basic electrolytes. The conductive material and any binder material used are combined to have equivalent mechanical properties, if applicable, of conventional polishing materials used in a conventional polishing article.

**[0105]** For example, the conductive polishing material, either alone or in combination with a binder material, has a hardness of about 100 or less on the Shore D Hardness scale for polymeric materials as described and measured by the American Society for Testing and Materials (ASTM), headquartered in Philadelphia, Pennsylvania. In one aspect, the conductive material has a hardness of about 80 or less on the Shore D Hardness scale for polymeric materials, such as a Shore D Hardness of between about 50 and about 80, for a conventional hard polishing pad. For example, a conductive polishing pad may have a Shore D Hardness between about 50 and about 70. The conductive polishing portion 110 generally includes a surface roughness of about 500 microns or less. The properties of the polishing pad are generally designed to reduce or minimize scratching of the substrate surfaces during mechanical polishing and when applying a bias to the substrate surface.

#### Polishing Article Structures

**[0106]** In one aspect, the polishing article is composed of a single layer of conductive polishing material described herein disposed on a support. In another aspects, the polishing article may comprise a plurality of material layers including at least one conductive material on the substrate surface or providing for a conductive surface for contacting a substrate and at least one article support portion or sub-pad.

**[0107]** Figure 3A is a partial cross-sectional view of one embodiment of a polishing article 205. Polishing article 205 illustrated in Figure 3 comprises a composite polishing article having a conductive polishing portion 310 for polishing a substrate surface and an article support, or sub-pad, portion 320.

**[0108]** The conductive polishing portion 310 may comprise a conductive polishing material including the conductive fibers and/or conductive fillers as described herein. For example, the conductive polishing portion 310 may include a conductive material comprising conductive fibers and/or conductive fillers dispersed in a polymeric material. Further, the conductive polishing portion may include one or more loops, coils, or rings of conductive fibers, or conductive fibers interwoven to form a conductive fabric or cloth. The conductive polishing portion 310 may also be comprised of multiple layers of conductive materials, for example, multiple layers of conductive cloth or fabric.

**[0109]** One example of the conductive polishing portion 310 includes graphite particles and gold coated nylon fibers disposed in polyurethane. Another example

includes graphite particles, carbon nanotubes, carbon fibers, and combinations thereof, disposed in polyurethane or silicone.

**[0110]** The article support portion 320 generally has the same or smaller diameter or width of the conductive polishing portion 310. However, the invention contemplates the article support portion 320 having a greater width or diameter than the conductive polishing portion 310. While the figures herein illustrate a circular conductive polishing portion 310 and article support portion 320, the invention contemplates that the conductive polishing portion 310, the article support portion 320, or both may have different shapes such as rectangular surfaces or elliptical surfaces. The invention further contemplates that the conductive polishing portion 310, the article support portion 320, or both, may form a linear web or belt of material.

**[0111]** The article support portion 320 may comprise inert materials in the polishing process and are resistant to being consumed or damaged during ECMP. For example, the article support portion may be comprised of a conventional polishing materials, including polymeric materials, for example, polyurethane and polyurethane mixed with fillers, polycarbonate, polyphenylene sulfide (PPS), ethylene-propylene-diene-methylene (EPDM), Teflon™ polymers, or combinations thereof, and other polishing materials used in polishing substrate surfaces. The article support portion 320 may be a conventional soft material, such as compressed felt fibers impregnated with urethane, for absorbing some of the pressure applied between the polishing article 205 and the carrier head 130 during processing. The soft material may have a Shore A hardness between about 20 and about 90.

**[0112]** Alternatively, the article support portion 320 may be made from a conductive material compatible with surrounding electrolyte that would not detrimentally affect polishing including conductive noble metals or a conductive polymer, to provide electrical conduction across the polishing article. Examples of noble metals include gold, platinum, palladium, iridium, rhenium, rhodium, rhenium, ruthenium, osmium, and combinations thereof, of which gold and platinum are preferred. Materials that are reactive with the surrounding electrolyte, such as copper, may be used if such materials are isolated from the surrounding electrolyte by an inert material, such as a conventional polishing material or a noble metal.

**[0113]** When the article support portion 320 is conductive, the article support portion 320 may have a greater conductivity, *i.e.*, lower resistivity, than the conductive polishing portion 310. For example, the conductive polishing portion 310 may have a resistivity of about 1.0  $\Omega\text{-cm}$  or less as compared to an article support portion 320 comprising platinum, which has a resistivity 9.81  $\mu\Omega\text{-cm}$  at 0°C. A conductive article support portion 320 may provide for uniform bias or current to minimize conductive resistance along the surface of the article, for example, the radius of the article, during polishing

for uniform anodic dissolution across the substrate surface. A conductive article support portion 320 may be coupled to a power source for transferring power to the conductive polishing portion 310.

[0114] Generally, the conductive polishing portion 310 is adhered to the article support portion 320 by a conventional adhesive suitable for use with polishing materials and in polishing processes. The adhesive may be conductive or dielectric depending on the requirements of the process or the desires of the manufacturer. The article support portion 320 may be affixed to a support, such as disc 206, by an adhesive or mechanical clamp. Alternatively, if polishing article 205 only includes a conductive polishing portion 310, the conductive polishing portion may be affixed to a support, such as disc 206, by an adhesive or mechanical clamp

[0115] The conductive polishing portion 310 and the article support portion 320 of the polishing article 205 are generally permeable to the electrolyte. A plurality of perforations may be formed, respectively, in the conductive polishing portion 310 and the article support portion 320 to facilitate fluid flow therethrough. The plurality of perforations allows electrolyte to flow through and contact the surface during processing. The perforations may be inherently formed during manufacturing, such as between weaves in a conductive fabric or cloth, or may be formed and patterned through the materials by mechanical means. The perforations may be formed partially or completely through each layer of the polishing article 205. The perforations of the conductive polishing portion 310 and the perforations of the article support portion 320 may be aligned to facilitate fluid flow therethrough.

[0116] Examples of perforations 350 formed in the polishing article 205 may include apertures in the polishing article having a diameter between about 0.02 inches (0.5 millimeters) and about 0.4 inches (10 mm). The thickness of the polishing article 205 may be between about 0.1 mm and about 5 mm. For example, perforations may be spaced between about 0.1 inches and about 1 inch from one another.

[0117] The polishing article 205 may have a perforation density between about 20% and about 80% of the polishing article in order to provide sufficient mass flow of electrolyte across the polishing article surface. However, the invention contemplates perforation densities below or above the perforation density described herein that may be used to control fluid flow therethrough. In one example, a perforation density of about 50% has been observed to provide sufficient electrolyte flow to facilitate uniform anodic dissolution from the substrate surface. Perforation density is broadly described herein as the volume of polishing article that the perforations comprise. The perforation density includes the aggregate number and diameter or size of the perforations, of the surface or body of the polishing article when perforations are formed in the polishing article 205.

[0118] The perforation size and density is selected to

provide uniform distribution of electrolyte through the polishing article 205 to a substrate surface. Generally, the perforation size, perforation density, and organization of the perforations of both the conductive polishing portion 310 and the article support portion 320 are configured and aligned to each other to provide for sufficient mass flow of electrolyte through the conductive polishing portion 310 and the article support portion 320 to the substrate surface.

[0119] Grooves may be disposed in the polishing article 205 to promote electrolyte flow across the polishing article 205 to provide effective or uniform electrolyte flow with the substrate surface for anodic dissolution or electroplating processes. The grooves may be partially formed in a single layer or through multiple layers. The invention contemplates grooves being formed in the upper layer or polishing surface that contacts the substrate surface. To provide increased or controlled electrolyte flow to the surface of the polishing article, a portion or plurality of the perforations may interconnect with the grooves. Alternatively, the all or none of the perforations may interconnect with the grooves disposed in the polishing article 205.

[0120] Examples of grooves used to facilitate electrolyte flow include linear grooves, arcuate grooves, annular concentric grooves, radial grooves, and helical grooves among others. The grooves formed in the article 205 may have a cross-section that is square, circular, semi-circular, or any other shape that may facilitate fluid flow across the surface of the polishing article. The grooves may intersect each other. The grooves may be configured into patterns, such as an intersecting X-Y pattern disposed on the polishing surface or an intersecting triangular pattern formed on the polishing surface, or combinations thereof, to improve electrolyte flow over the surface of the substrate.

[0121] The grooves may be spaced between about 30 mils and about 300 mils apart from one another. Generally, grooves formed in the polishing article have a width between about 5 mils and about 30 mils, but may vary in size as required for polishing. An example of a groove pattern includes grooves of about 10 mils wide spaced about 60 mils apart from one another. Any suitable groove configuration, size, diameter, cross-sectional shape, or spacing may be used to provide the desired flow of electrolyte. Additional cross sections and groove configurations are more fully described in co-pending United States Patent Provisional Application Serial No. 60/328,434, filed on October 11, 2001, entitled "Method And Apparatus For Polishing Substrates", which is incorporated herein by reference to the extent not inconsistent with the claims and disclosure herein.

[0122] Electrolyte transport to the surface of the substrate may be enhanced by intersecting some of the perforations with the grooves to allow electrolyte to enter through one set of perforation, be evenly distributed around the substrate surface by the grooves, used in processing a substrate, and then processing electrolyte

is refreshed by additional electrolyte flowing through the perforations. An example of a pad perforation and grooving is more fully described in United States Patent Application Serial No. 10/026,854, filed December 20, 2001, which is incorporated by reference to the extent not inconsistent with the aspects and claims herein.

**[0123]** Examples of polishing articles having perforations and grooves are as follows. Figure 4 is a top plan view of one embodiment of a grooved polishing article. A round pad 440 of the polishing article 205 is shown having a plurality of perforations 446 of a sufficient size and organization to allow the flow of electrolyte to the substrate surface. The perforations 446 can be spaced between about 0.1 inches and about 1 inch from one another. The perforations may be circular perforations having a diameter of between about 0.02 inches (0.5 millimeters) and about 0.4 inches (10 mm). Further the number and shape of the perforations may vary depending upon the apparatus, processing parameters, and ECMP compositions being used.

**[0124]** Grooves 442 are formed in the polishing surface 448 of the polishing article 205 therein to assist transport of fresh electrolyte from the bulk solution from basin 202 to the gap between the substrate and the polishing article. The grooves 442 may have various patterns, including a groove pattern of substantially circular concentric grooves on the polishing surface 448 as shown in Figure 4, an X-Y pattern as shown in Figure 5 and a triangular pattern as shown in Figure 6.

**[0125]** Figure 5 is a top plan view of another embodiment of a polishing pad having grooves 542 disposed in an X-Y pattern on the polishing portion 548 of a polishing pad 540. Perforations 546 may be disposed at the intersections of the vertically and horizontally disposed grooves, and may also be disposed on a vertical groove, a horizontal groove, or disposed in the polishing article 548 outside of the grooves 542. The perforations 546 and grooves 542 are disposed in the inner diameter 544 of the polishing article and the outer diameter 550 of the polishing pad 540 may be free of perforations and grooves and perforations.

**[0126]** Figure 6 is another embodiment of patterned polishing article 640. In this embodiment, grooves may be disposed in an X-Y pattern with diagonally disposed grooves 645 intersecting the X-Y patterned grooves 642. The diagonal grooves 645 may be disposed at an angle from any of the X-Y grooves 642, for example, between about 30° and about 60° from any of the X-Y grooves 642. Perforations 646 may be disposed at the intersections of the X-Y grooves 642, the intersections of the X-Y grooves 642 and diagonal grooves 645, along any of the grooves 642 and 645, or disposed in the polishing article 648 outside of the grooves 642 and 645. The perforations 646 and grooves 642 are disposed in the inner diameter 644 of the polishing article and the outer diameter 650 of the polishing pad 640 may be free of perforations and grooves.

**[0127]** Additional examples of groove patterns, such

as spiraling grooves, serpentine grooves, and turbine grooves, are more fully described in co-pending United States Patent Provisional Application Serial No. 60/328,434, filed on October 11, 2001, entitled "Method And Apparatus For Polishing Substrates", which is incorporated herein by reference to the extent not inconsistent with the claims and disclosure herein.

### Conductive Polishing Surfaces

**[0128]** Figure 7A is a top sectional view of one embodiment of a conductive cloth or fabric 700 that may be used to form a conductive polishing portion 310 of the polishing article 205. The conductive cloth of fabric 700 is composed of interwoven fibers 710 coated with a conductive material as described herein. The fabric of interwoven fibers coated with a conductive material may include a plurality of fibers coated with a conductive material interwoven to form a fabric. The fabric may also include a plurality of interwoven fibers to form a fabric that is then coated with a conductive material. The fabric may also be formed by a combination of the two processes for forming the fabric of interwoven fibers coated with a conductive material.

**[0129]** In one embodiment, a weave or basket-weave pattern of the interwoven fibers 710 in the vertical 720 and horizontal 730 directions is illustrated in Figure 7A. The invention contemplates other form of fabrics, such as yarns, or different interwoven, web, or mesh patterns to form the conductive cloth or fabric 700. In one aspect, the fibers 710 are interwoven to provide passages 740 in the fabric 700. The passages 740 allow electrolyte or fluid flow, including ions and electrolyte components, through the fabric 700. The conductive fabric 700 may be disposed in a polymeric binder, such as polyurethane. Conductive fillers may also be disposed in such a polymeric binder.

**[0130]** Figure 7B is a partial cross-sectional view of the conductive cloth or fabric 700 disposed on the article support portion 320 of the article 205. The conductive cloth or fabric 700 may be disposed as one or more continuous layers over the article support portion 320 including any perforations 350 formed in the article support portion 320. The cloth or fabric 700 may be secured to the article support portion 320 by an adhesive. The fabric 700 is adapted to allow electrolyte flow through the fibers, weaves, or passages formed in the cloth or fabric 700 when immersed in an electrolyte solution.

**[0131]** Alternatively, the fabric 700 may also be perforated to increase electrolyte flow therethrough if the passages 740 are determined to not be sufficient to allow effective flow of electrolyte through the fabric 700, i.e., metal ions cannot diffuse through. The fabric 700 is typically adapted or perforated to allow flow rates of electrolyte solutions of up to about 20 gallons per minute.

**[0132]** Figure 7C is a partial cross-sectional view of the cloth or fabric 700 may be patterned with perforations 750 to match the pattern of perforations 350 in the

article support portion 320. Alternatively, some or all of the perforations 750 of the conductive cloth or fabric 700 may not be aligned with the perforations 350 of the article support portion 320. Aligning or non-aligning of perforations allow the operator or manufacturer to control the volume or flow rate of electrolyte through the polishing article to contact the substrate surface.

**[0133]** An example of the fabric 700 is an interwoven basket weave of between about 8 and about 10 fibers wide with the fiber comprising a nylon fiber coated with gold. An example of the fiber is a nylon fiber, about 0.1  $\mu\text{m}$  of cobalt, copper, or nickel material disposed on the nylon fiber, and about 2  $\mu\text{m}$  of gold disposed on the cobalt, copper, or nickel material.

**[0134]** Alternatively, a conductive mesh may be used in place of the conductive cloth or fabric 700. The conductive mesh may comprises conductive fibers, conductive fillers, or at least a portion of a conductive cloth 700 disposed in or coated with a conductive binder. The conductive binder may comprise a nonmetallic conductive polymer or a composite of conductive material disposed in a polymeric compound. A mixture of a conductive filler, such as graphite powder, graphite flakes, graphite fibers, carbon fibers, carbon powder, carbon black, or fibers coated in a conductive material, and a polymeric material, such as polyurethane, may be used to form the conductive binder. The fibers coated with a conductive material as described herein may be used as a conductive filler for use in the conductive binders. For example, carbon fibers or gold-coated nylon fibers may be used to form a conductive binder.

**[0135]** The conductive binder may also include additives if needed to assist the dispersion of conductive fillers and/or fibers, improve adhesion between polymer and fillers and/or fibers, and improve adhesion between the conductive foil and the conductive binder, as well as to improve of mechanical, thermal and electrical properties of conductive binder. Examples of additives to improve adhesion include epoxies, silicones, urethanes, polyimides, or combinations thereof for improved adhesion.

**[0136]** The composition of the conductive fillers and/or fibers and polymeric material may be adapted to provide specific properties, such as conductivity, abrasion properties, durability factors. For example conductive binders comprising between about 2 wt.% and about 85 wt.% of conductive fillers may be used with the articles and processes described herein. Examples of materials that may be used as conductive fillers and conductive binders are more fully described in U.S. Patent Application Serial No. 10/033,732, filed December 27, 2001, which is incorporated herein by reference to the extent not inconsistent with the disclosure or claimed aspects herein.

**[0137]** The conductive binder may have a thickness of between about 1 microns and 10 millimeters, such as between about 10 microns and about 1 millimeter thick. Multiple layers of conductive binders may be applied to

the conductive mesh. The conductive mesh may be used in the same manner as the conductive cloth or fabric 700 as shown in Figures 7B and 7C. The conductive binder may be applied in multiple layers over the conductive mesh. In one aspect, the conductive binder is applied to the conductive mesh after the mesh has been perforated to protect the portion of the mesh exposed from the perforation process.

**[0138]** Additionally, a conductive primer may be disposed on the conductive mesh before application of a conductive binder to improve adhesion of the conductive binder to the conductive mesh. The conductive primer may be made of similar material to the conductive binder fibers with a composition modified to produce properties having a greater intermaterial adhesion than the conductive binder. Suitable conductive primer materials may have resistivities below about 100  $\Omega\text{-cm}$ , such as between 0.001  $\Omega\text{-cm}$  and about 32  $\Omega\text{-cm}$ .

**[0139]** Alternatively, a conductive foil may be used in place of the conductive cloth or fabric 700 as shown in Figure 7D. The conductive foil generally includes a metal foil 780 disposed in or coated with a conductive binder 790 on the support layer 320. Examples of material forming metal foils include metal coated fabrics, conductive metals such as copper, nickel, and cobalt, and noble metals, such as gold, platinum, palladium, iridium, rhodium, rhenium, ruthenium, osmium, and combinations thereof, of which gold and platinum are preferred.

**[0140]** The conductive foil may also include a nonmetallic conductive foil sheet, such as a copper sheet, carbon fiber woven sheet foil. The conductive foil may also include a metal coated cloth of a dielectric or conductive material, such as copper, nickel, or gold coating a cloth of nylon fibers. The conductive foil may also comprise a fabric of conductive or dielectric material coated with a conductive binder material as described herein. The conductive foil may also comprise a wire frame, screen or mesh of interconnecting conductive metal wires or strips, such as copper wire, which may be coated with a conductive binder material as described herein. The invention contemplates the use of other material in forming the metal foil described herein.

**[0141]** A conductive binder 790 as described herein may encapsulate the metal foil 780, which allows the metal foil 780 to be conductive metals that are observed to react with the surrounding electrolyte, such as copper. The conductive foil may be perforated with a plurality of perforation 750 as described herein. While not shown, the conductive foil may be coupled to a conductive wire to power supply to bias the polishing surface. While not shown, the metal foil 780 may also be grooved.

**[0142]** The conductive binder 790 may be as described for the conductive mesh or fabric 700 and may be applied in multiple layers over the metal foil 780. In one aspect, the conductive binder 790 is applied to the metal foil 780 after the metal foil 780 has been perforated to protect the portion of the metal foil 780 exposed

from the perforation process.

[0143] The conductive binder described herein may be disposed onto conductive fabric 700, foil 780, or mesh by casting liquid state adhesive or binder onto the fabric 700, foil 780 or mesh. The binder is then solidified on the fabric, foil or mesh after drying and curing. Other suitable processing methods including injection mold, compression mold, lamination, autoclave, extrusion, or combinations thereof may be used to encapsulate the conductive fabric, mesh, or foil. Both thermoplastic and thermosetting binders may be used for this application.

[0144] Adhesion between the conductive binder and the metal foil components of the conductive foil may be enhanced by perforating the metal foil with a plurality of perforations having a diameter or width between about 0.1  $\mu\text{m}$  and about 1 mm or by applying a conductive primer between the metal foil and the conductive binder. The conductive primer may be of the same material as the conductive primer for the mesh described herein.

#### Conductive Elements in Polishing Surfaces

[0145] In another aspect, the conductive fibers and fillers described herein may be used to form distinct conductive elements disposed in a polishing material to form the conductive polishing article 205 of the invention. The polishing material may be a conventional polishing material or a conductive polishing material, for example, a conductive composite of conductive fillers or fibers disposed in the polymer as described herein. The surface of the conductive elements may form a plane with the surface of the polishing article or may extend above a plane of the surface of the polishing article. Conductive elements may extend up to about 5 millimeters above the surface of the polishing article.

[0146] While the following illustrate the use of conductive elements having a specific structure and arrangement in the polishing material, the invention contemplates that individual conductive fibers and fillers, and materials made therefrom, such as fabrics, may also be considered conductive elements. Further, while not shown, the following polishing article descriptions may include polishing articles having perforation and grooving patterns described herein and shown in Figures 4-6, with configurations to the patterns to incorporate the conductive elements described herein as follows.

[0147] Figures 8A-8B depict a top and a cross-sectional schematic view of one embodiment of a polishing article 800 having conductive elements disposed therein. The polishing article 800 generally comprises a body 810 having a polishing surface 820 adapted to contact the substrate while processing. The body 810 typically comprises a dielectric or polymeric material, such as a dielectric polymer material, for example, polyurethane.

[0148] The polishing surface 820 has one or more openings, grooves, trenches, or depressions 830 formed therein to at least partially receive conductive elements 840. The conductive elements 840 may be

generally disposed to have a contact surface 850 co-planar or extending above a plane defined by the polishing surface 820. The contact surface 850 is typically configured, such as by having a compliant, elastic, flexible, or pressure moldable surface, to maximize electrical contact of the conductive elements 840 when contacting the substrate. During polishing, a contact pressure may be used to urge the contact surface 850 into a position co-planar with the polishing surface 820.

[0149] The body 810 is generally made permeable to the electrolyte by a plurality of perforations 860 formed therein as described herein. The polishing article 800 may have a perforation density between about 20% and about 80% of the surface area of the polishing article 810 to provide sufficient electrolyte flow to facilitate uniform anodic dissolution from the substrate surface.

[0150] The body 810 generally comprises a dielectric material such as the conventional polishing materials described herein. The depressions 830 formed in the body 810 are generally configured to retain the conductive elements 840 during processing, and accordingly may vary in shape and orientation. In the embodiment depicted in Figure 8A, the depressions 830 are grooves having a rectangular cross section disposed across the polishing article surface and forming an interconnecting "X" or cross pattern 870 at the center of the polishing article 800. The invention contemplates additional cross sections, such as inverse trapezoidal and rounded curvature where the groove contacts the substrate surface as described herein.

[0151] Alternatively, the depressions 830 (and conductive elements 840 disposed therein) may be disposed at irregular intervals, be orientated radially, parallel, or perpendicular, and may additionally be linear, curved, concentric, involute curves, or other cross-sectional areas.

[0152] Figure 8C is a top schematic view of a series of individual conductive elements 840 radially disposed in the body 810, each element 840 separated physically or electrically by a spacer 875. The spacer 875 may be a portion of dielectric polishing material or a dielectric interconnect for the elements, such as a plastic interconnect. Alternatively, the spacer 875 may be a section of the polishing article devoid of either the polishing material or conductive elements 840 to provide an absence of physical connection between the conductive elements 840. In such a separate element configuration, each conductive element 840 may be individually connected to a power source by a conductive path 890, such as a wire.

[0153] Referring back to figures 8A and 8B, the conductive elements 840 disposed in the body 810 are generally provided to produce a bulk resistivity or a bulk surface resistivity of about 20  $\Omega\text{-cm}$  or less. In one aspect of the polishing article, the polishing article has a resistivity of about 2  $\Omega\text{-cm}$  or less. The conductive elements 840 generally have mechanical properties that do not degrade under sustained electric fields and are resistant

to degradation in acidic or basic electrolytes. The conductive elements 840 are retained in the depressions 830 by press fit, clamping, adhesive, or by other methods.

**[0154]** In one embodiment, the conductive elements 840 are sufficiently compliant, elastic, or flexible to maintain electrical contact between the contact surface 850 and the substrate during processing. Sufficient compliant, elastic, or flexible materials for the conductive element 840 may have an analogous hardness of about 100 or less on the Shore D Hardness scale compared to the polishing material. A conductive element 840 having an analogous hardness of about 80 or less on the Shore D Hardness scale for polymeric materials may be used. A compliant material, such as flexible or bendable fibers of material, may also be used as the conductive elements 840.

**[0155]** In the embodiment depicted in Figures 8A and 8B, the conductive elements 840 are embedded in the polishing surface 810 disposed on an article support or sub-pad 815. Perforations 860 are formed through both polishing surface 810 and the article support 815 around conductive elements 840.

**[0156]** An example of the conductive elements 840 includes dielectric or conductive fibers coated with a conductive material or conductive fillers blended with a polymeric material, such as a polymer based adhesive, to make a conductive (and wear resistant) composite as described herein. The conductive elements 840 may also comprise conductive polymeric material or other conductive materials as described herein to improve electrical properties. For example, the conductive elements comprise a composite of a conductive epoxy and a conductive fiber comprising a nylon fiber coated with gold, such as a nylon fiber coated with about 0.1  $\mu\text{m}$  of cobalt, copper, or nickel disposed on the nylon fiber, and about 2  $\mu\text{m}$  of gold disposed on the a nylon fiber, and carbon or graphite fillers to improve the composite's conductivity, which is deposited in a body of polyurethane.

**[0157]** Figure 8D is a cross-sectional schematic view of another embodiment of a polishing article 800 having conductive elements disposed therein. The conductive elements 800 may be generally disposed to have a contact surface co-planar or extending above a plane defined by the polishing surface 820. The conductive elements 840 may include the conductive fabric 700, as described herein, disposed, encapsulated or wrapped around a conductive member 845. Alternatively individual conductive fibers and/or fillers may be disposed, encapsulated, or wrapped around the conductive member 845. The conductive member 845 may comprise a metal, such as a noble metal described herein, or other conductive materials, such as copper, suitable for use in electropolishing processes. The conductive element 840 may also comprise a composite of the fabric and a binder material as described herein with the fabric forming an outer contact portion of the conductive element

860 and the binder typically forming an inner support structure. The conductive element 860 may also comprise a hollow tube having a rectangular cross-sectional area with the walls of the tube formed of rigid conductive fabric 700 and a bonding agent as described herein.

**[0158]** A connector 890 is utilized to couple the conductive elements 840 to a power source (not shown) to electrically bias the conductive elements 840 during processing. The connector 890 is generally a wire, tape or other conductor compatible with process fluids or having a covering or coating that protects the connector 890 from the process fluids. The connector 890 may be coupled to the conductive elements 840 by molding, soldering, stacking, brazing, clamping, crimping, riveting, fastening, conductive adhesive or by other methods or devices. Examples of materials that may be utilized in the connector 890 include insulated copper, graphite, titanium, platinum, gold, aluminum, stainless steel, and HASTELOY® conductive materials among other materials.

**[0159]** Coatings disposed around the connectors 890 may include polymers such as fluorocarbons, poly-vinyl chloride (PVC) and polyimide. In the embodiment depicted in Figure 8A, one connector 890 is coupled to each conductive element 840 at the perimeter of the polishing article 800. Alternatively, the connectors 890 may be disposed through the body 810 of the polishing article 800. In yet another embodiment, the connector 890 may be coupled to a conductive grid (not shown) disposed in the pockets and/or through the body 810 that electrically couples the conductive elements 840.

**[0160]** Figure 9A depicts another embodiment of a polishing material 900. The polishing material 900 includes a body 902 having one or more at least partially conductive elements 904 disposed on a polishing surface 906. The conductive elements 904 generally comprise a plurality of fibers, strands, and/or flexible fingers that are compliant or elastic and adapted to contact a substrate surface while processing. The fibers are comprised of an at least partially conductive material, such as a fiber composed of a dielectric material coated with a conductive material as described herein. The fibers may also be solid or hollow in nature to decrease or increase the amount of compliance or flexibility of the fibers.

**[0161]** In the embodiment depicted in Figure 9A, the conductive elements 904 are a plurality of conductive sub-elements 913 coupled to a base 909. The conductive sub-elements 913 include the at least partially electrically conductive fibers described herein. An example of the sub-elements 913 include a nylon fiber coated with gold as described herein or carbon fiber. The base 909 also comprises an electrically conductive material and is coupled to a connector 990. The base 909 may also be coated by a layer of conductive material, such as copper, that dissolves from the polishing pad article during polishing, which is believed to extend the processing duration of the conductive fibers.

[0162] The conductive elements 904 generally are disposed in a depression 908 formed in the polishing surface 906. The conductive elements 904 may be orientated between 0 and 90 degrees relative to the polishing surface 906. In embodiments where the conductive elements 904 are orientated parallel to the polishing surface 906, the conductive elements 904 may partially be disposed on the polishing surface 906.

[0163] The depressions 908 have a lower mounting portion 910 and an upper, clearance portion 912. The mounting portion 910 is configured to receive the base 909 of the conductive elements 904, and retain the conductive elements 904 by press fit, clamping, adhesive, or by other methods. The clearance portion 912 is disposed where the depression 908 intersects the polishing surface 906. The clearance portion 912 is generally larger in cross section than the mounting portion 910 to allow the conductive elements 904 to flex when contacting a substrate while polishing without being disposed between the substrate and the polishing surface 906.

[0164] Figure 9B depicts another embodiment of a polishing article 900 having a conducting surface 940 and a plurality of discrete conductive elements 920 formed thereon. The conductive elements 920 comprise fibers of dielectric material coated by a conductive material are vertically displaced from the conducting surface 940 of the polishing article 205 and are horizontally displaced from each other. The conducting elements 920 of the polishing article 900 are generally orientated between 0 to 90 degrees relative to a conducting surface 940 and can be inclined in any polar orientation relative to a line normal to the conducting surface 940. The conductive elements 920 may be formed across the length of the polishing pads, as shown in Figure 9B or only may be disposed in selected areas of the polishing pad. The contact height of the conductive elements 920 above the polishing surface may be up to about 5 millimeters. The diameter of the material comprising the conductive element 920 is between about 1 mil (thousandths of an inch) and about 10 mils. The height above the polishing surface and a diameter of the conductive elements 920 may vary upon the polishing process being performed.

[0165] The conductive elements 920 are sufficiently compliant or elastic to deform under a contact pressure while maintaining an electrical contact with a substrate surface with reduced or minimal scratching of the substrate surface. In the embodiment shown in Figure 9A and 9B, the substrate surface may only contacts the conductive elements 920 of the polishing article 205. The conductive elements 920 are positioned so as to provide an uniform current density over the surface of the polishing article 205.

[0166] The conductive elements 920 are adhered to the conducting surface by a non-conductive, or dielectric, adhesive or binder. The non-conductive adhesive may provide a dielectric coating to the conducting surface 940 to provide an electrochemical barrier between the conducting surface 940 and any surrounding elec-

trolyte. The conducting surface 940 may be in the form of a round polishing pad or a linear web or belt of polishing article 205. A series of perforations (not shown) may be disposed in the conducting surface 940 for provided flow of electrolyte therethrough.

[0167] While not shown, the conductive plate may be disposed on a support pad of conventional polishing material for positioning and handling of the polishing article 900 on a rotating or linear polishing platen.

[0168] Figure 10A depicts a schematic perspective view of one embodiment of a polishing article 1000 comprised of conductive element 1004. Each conductive element 1004 generally comprises a loop or ring 1006 having a first end 1008 and a second end 1010 disposed in a depression 1012 formed in the polishing surface 1024. Each conductive element 1004 may be coupled to an adjoining conductive element to form a plurality of loops 1006 extending above the polishing surface 1024.

[0169] In the embodiment depicted in Figure 10A, each loop 1006 is fabricated from a fiber coated by a conductive material and are coupled by a tie wire base 1014 adhered to the depression 1012. An example of the loop 1006 is a nylon fiber coated with gold.

[0170] The contact height of the loop 1006 above the polishing surface may be between about 0.5 millimeter and about 2 millimeters and the diameter of the material comprising the loop may be between about 1 mil (thousandths of an inch) and about 50 mils. The tie wire base 1014 may be a conductive material, such as titanium, copper, platinum, or platinum coated copper. The tie wire base 1014 may also be coated by a layer of conductive material, such as copper, that dissolves from the polishing pad article during polishing. The use of a layer of conductive material on the tie wire base 1014 is believed to be a sacrificial layer that dissolves in preference of the underlying loop 1006 material or tie wire base 1014 material to extend the life of the conductive element 1004. The conductive elements 1004 may be orientated between 0 to 90 degrees relative to a polishing surface 1024 and can be inclined in any polar orientation relative to a line normal to the polishing surface 1024. The conductive elements 1004 are coupled to a power source by electrical connectors 1030.

[0171] Figure 10B depicts a schematic perspective view of another embodiment of a polishing article 1000 comprised of conductive element 1004. The conductive element 1004 comprises a singular coil 1005 of a wire composed of a fiber coated with a conductive material as described herein. The coil 1005 is coupled to a conductive member 1007 disposed on a base 1014. The coil 1005 may be encircle the conductive member 1007, encircle the base 1014, or be adhered to the surface of the base 1014. The conductive bar may comprise a conductive material, such as gold, and generally comprises a conductive material that is chemically inert, such as gold or platinum, with any electrolyte used in a polishing process. Alternatively, a layer 1009 of sacrificial material, such as copper, is disposed on the base 1014. The

layer 1009 of sacrificial material is generally a more chemically reactive material, such as copper, than the conductive member 1007 for preferential removal of the chemically reactive material compared to the material of the conductive member 1007 and the coil 1005, during an electropolishing aspect, or anodic dissolution aspect, of the polishing process. The conductive member 1007 may be coupled to a power source by electrical connectors 1030.

**[0172]** A biasing member may be disposed between the conductive elements and the body to provide a bias that urges the conductive elements away from the body and into contact with a substrate surface during polishing. An example of a biasing member 1018 is shown in Figure 10B. However, the invention contemplates that the conductive elements shown herein, for example in Figures 8A-8D, 9A, 10A-10D, may use a biasing member. The biasing member may be a resilient material or device including a compression spring, a flat spring, a coil spring, a foamed polymer such as foamed polyurethane (e.g., PORON® polymer), an elastomer, a bladder or other member or device capable of biasing the conductive element. The biasing member may also be a compliant or elastic material, such as compliant foam or aird soft tube, capable of biasing the conductive element against and improve contact with the substrate surface being polished. The conductive elements biased may form a plane with the surface of the polishing article or may extend above a plane of the surface of the polishing article.

**[0173]** Figure 10C shows a schematic perspective view of another embodiment of a polishing article 1000 having a plurality of conductive elements 1004, disposed in a radial pattern from the center of the substrate to the edge. The plurality of conductive elements may be displaced from each other at intervals of 15°, 30°, 45°, 60°, and 90° degrees, or any other combinations desired. The conductive elements 1004 are generally spaced to provide as uniform application of current or power for polishing of the substrate. The conductive elements may be further spaced so as to not contact each other. Wedge portions 1004 of a dielectric polishing material of the body 1026 may be configured to electrically isolate the conductive elements 1004. A spacer or recessed area 1060 is also formed in the polishing article to also isolate the conductive elements 1004 from each other. The conductive elements 1004 may be in the form of loops as shown in Figure 10A or vertical extending fibers as shown in Figure 9B.

**[0174]** Figure 10D depicts a schematic perspective view of an alternative embodiment of the conductive element 1004 of Figure 10A. The conductive element 1004 comprises a mesh or fabric of interwoven conductive fibers 1006 as described herein having a first end 1008 and a second end 1010 disposed in a depression 1012 formed in the polishing surface 1024 to form one continuous conductive surface for contact with the substrate. The mesh or fabric may be of one or more layers

of interwoven fibers. The mesh or fabric comprising the conductive element 1004 is illustrated as a single layer in Figure 10D. The conductive element 1004 may be coupled to a conductive base 1014 and may extend above the polishing surface 1024 as shown in Figure 10A. The conductive element 1004 may be coupled to a power source by electrical connectors 1030 connected to the conductive base 1014.

**[0175]** Figure 10E shows a partial schematic perspective view of another embodiment of forming the conductive elements 1004 having loops 1006 formed therein and securing the conductive elements to the body 1026 of the polishing article. Passages 1050 are formed in the body 1024 of the polishing article intersecting grooves 1070 for the conductive elements 1004. An insert 1055 is disposed in the passages 1050. The insert 1055 comprises a conductive material, such as gold or the same material as the conductive element 1006. Connectors 1030 may then be disposed in the passages 1050 and contacted with the insert 1055. The connectors 1030 are coupled to a power source. Ends 1075 of the conductive element 1004 may be contacted with the insert 1055 for flow of power therethrough. The ends 1075 of the conductive element 1004 and the connectors 1030 are then secured to the conductive insert 1055 by dielectric inserts 1060. The invention contemplated using the passages for every loop 1006 of the conductive element 1004, at intervals along the length of the conductive element 1004, or only at the extreme ends of the conductive element 1004.

**[0176]** Figures 11A-C are a series of schematic side views illustrating the elastic ability of the loops or rings of conductive materials described herein. A polishing article 1100 comprises a polishing surface 1110 disposed on a sub-pad 1120 formed over a pad support 1130 with grooves or depressions 1140 therein. A conductive element 1140 comprising a loop or ring 1150 of a dielectric material coated by a conductive material is disposed on a tie base 1155 in the depression 1170 and coupled with an electrical contact 1145. A substrate 1160 is contacted with the polishing article 1100 and moved in relative motion with the surface of the polishing article 1100. As the substrate contacts the conductive element 1140, the loop 1150 compresses into the depression 1140 while maintaining electrical contact with the substrate 1160 as shown in Figure 11B. When the substrate is moved a sufficient distance to no longer contact the conductive element 1140, the elastic loop 1150 returns to the uncompressed shape for additional processing as shown in Figure 11C.

**[0177]** Further examples of conductive polishing pads are described in United States Provisional Patent Application Serial Number 10/033,732, filed December 27, 2001, which is incorporated by reference to the extent not inconsistent with the aspects and claims herein.

## Power Application

**[0178]** Power may be coupled into the polishing articles 205 described above by using a connector as described herein or a power transference device. A power transference device is more fully detailed in United States Provisional Patent Application Serial Number 10/033,732, filed December 27, 2001, which is incorporated by reference to the extent not inconsistent with the aspects and claims herein.

**[0179]** Referring back to Figures 11A-11C, power may be coupled to conductive elements 1140 by the use of electrical contacts 1145 comprising conductive plates or mounts disposed in the grooves or depressions 1170 formed in the polishing pad. In the embodiment shown in Figure 11A, the conductive elements 1140 are mounted on plates of a metal, such as gold, which are mounted on a support, such as disc 206, with the polishing article 1100 as shown in Figure 2. Alternatively, the electrical contacts may be disposed on a polishing pad material between a conductive elements and a polishing pad material, for example, between the conductive element 840 and the body 810 as shown in Figures 8A and 8B. The electrical contacts are then coupled to a power source by leads (not shown) as described above in Figures 8A-8D.

**[0180]** Figures 12A-12D are top and side schematic view of embodiments of a polishing article having extensions connected to a power source (not shown). The power source provides the current carrying capability, *i.e.*, the anodic bias to a substrate surface for anodic dissolution in an ECMP process. The power source may be connected to the polishing article by one or more conductive contacts disposed around the conductive polishing portion and/or the article support portion of the polishing article. One or more power sources may be connected to the polishing article by the one or more contacts to allow for generating variable bias or current across portion of the substrate surface. Alternatively, one or more leads may be formed in the conductive polishing portion and/or the article support portion, which are coupled to a power source.

**[0181]** Figure 12A is a top plan view of one embodiment of a conductive polishing pad coupled to a power source by a conductive connector. The conductive polishing portion may have extensions, for example, a shoulder or individual plugs, formed in the conductive polishing portion 1210 with a greater width or diameter than the article support portion 1220. The extensions are coupled to a power source by a connector 1225 to provide electrical current to the polishing article 205. In Figure 12B, extensions 1215 may be formed to extend parallel or laterally from the plane of the conductive polishing portion 1210 and extending beyond the diameter of the polishing support portion 1220. The pattern of the perforation and grooving are as shown in Figure 6.

**[0182]** Figure 12B is a cross-section schematic view of one embodiment of a connector 1225 coupled to a

power source (not shown) via a conductive pathway 1232, such as a wire. The connector comprises an electrical coupling 1234 connected to the conductive pathway 1232 and electrically coupled to the conductive polishing portion 1210 of the extension 1215 by a conductive fastener 1230, such as a screw. A bolt 1238 may be coupled to the conductive fastener 1230 securing the conductive polishing portion 1210 therebetween. Spacers 1236, such as washer, may be disposed between the conductive polishing portion 1210 and the fastener 1230 and bolt 1238. The spacers 1236 may comprise a conductive material. The fastener 1230, the electrical coupling 1234, the spacers 1236, and the bolt 1238 may be made of a conductive material, for example, gold, platinum, titanium, aluminum, or copper. If a material that may react with the electrolyte is used, such as copper, the material may be covered in a material that is inert to reactions with the electrolyte, such as platinum. While not shown, alternative embodiments of the conductive fastener may include a conductive clamp, conductive adhesive tape, or a conductive adhesive.

**[0183]** Figure 12C is a cross-section schematic view of one embodiment of a connector 1225 coupled to a power source (not shown) via a support 1260, such as the upper surface of a platen or disc 206 as shown in Figure 2. The connector 1225 comprises a fastener 1240, such as a screw or bolt having sufficient length to penetrate through the conductive polishing portion 1210 of the extension 1215 to couple with the support 1260. A spacer 1242 may be disposed between the conductive polishing portion 1210 and the fastener 1240.

**[0184]** The support is generally adapted to receive the fastener 1240. An aperture 1246 may be formed in the surface of the support 1260 to receive the fastener as shown in Figure 12C. Alternatively, an electrical coupling may be disposed between the fastener 1240 and the conductive polishing portion 1210 with the fastener coupled with a support 1260. The support 1260 may be connected to a power source by a conductive pathway 1232, such as a wire, to a power source external to a polishing platen or chamber or a power source integrated into a polishing platen or chamber to provide electrical connection with the conductive polishing portion 1210. The conductive path 1232 may be integral with the support 1260 or extend from the support 1260 as shown in Figure 12B.

**[0185]** In a further embodiment, the fastener 1240 may be an integrated extension of the support 1260 extending through the conductive polishing portion 1215 and secured by a bolt 1248 as shown in Figure 12D.

**[0186]** Figures 12E and 12F show side schematic and exploded perspective views of another embodiment of providing power to a polishing article 1270 having a power coupling 1285 disposed between a polishing portion 1280 and a article support portion 1290. The polishing portion 1280 may be made of a conductive polishing material as described herein or include a plurality of conductive elements 1275 as described herein. The

conductive elements 1275 may be physically isolated from one another as shown in Figure 12F. The conductive elements 1275 formed in the polishing surface are adapted to electrically contact the power coupling 1285, such as by a conductive base of the element.

**[0187]** The power coupling 1285 may comprise a wire interconnecting elements 1275, multiple parallel wires interconnecting elements 1275, multiple wires independently connecting elements 1275, or a wire mesh interconnecting elements connecting elements 1275 to one or more power sources. Independent power sources coupled to independent wires and elements may have varied power applied while interconnected wires and elements may provide uniform power to the elements. The power coupling may cover a portion or all of the diameter or width of the polishing article. The power coupling 1285 in Figure 12F is an example of a wire mesh interconnecting elements connecting elements 1275. The power coupling 1285 may be connected to a power source by a conductive pathway 1287, such as a wire, to a power source external to a polishing platen or chamber or a power source integrated into a polishing platen or chamber.

**[0188]** While foregoing is directed to various embodiments of the invention, other and further embodiments of the invention may be devised without departing from the basic scope thereof, and the scope thereof is determined by the claims that follow.

#### Claims

1. A polishing article for processing a substrate, comprising:
  - a body having a surface adapted to polish the substrate; and
  - at least one conductive element embedded at least partially in the body, the conductive element comprising fibers coated with a conductive material, conductive fillers, or combinations thereof.
2. The polishing article of claim 1, wherein the fibers comprise a polymeric material selected from the group of polyamides, nylon polymer, polyurethane, polyester, polypropylene, polyethylene, polycarbonate, diene containing polymers, polystyrene, polyacrylonitrile ethylene styrene, acrylic polymers, and combinations thereof, and the conductive material comprises a metal, carbon material, a conductive ceramic material, a metal inorganic material or combinations thereof, and the conductive fillers comprise carbon powder, carbon fibers, carbon nanotubes, carbon nanofoam, carbon aerogels, graphite, conductive polymers, conductive fibers, dielectric or conductive particles coated with a conductive material, dielectric filler materials coated in
- conductive materials, conductive inorganic particles, conductive ceramic particles, and combinations thereof.
3. The polishing article of claim 1, wherein the body comprises a polymeric material from the group of polyester, polyurethane, polycarbonate, polystyrene, polyphenylene sulfide, felt fibers impregnated with urethane, and combinations thereof.
4. The polishing article of claim 1 or claim 2, wherein the fiber coated with the conductive material further comprises a nucleation material or a binder material disposed between the fiber and the conductive material.
5. The polishing article of any of claims 1 to 3, wherein the polishing article comprises polyamide fibers with gold disposed thereon and graphite disposed in a polyurethane binder or graphite, carbon nanotubes, carbon fibers, and combinations thereof disposed in polyurethane or silicone.
6. The polishing article of any of claims 1 to 5, wherein the body further comprises a plurality of grooves or perforations formed at least partially therein.
7. The polishing article of claim 6, wherein the at least one conductive element is disposed in one or more of the plurality of grooves formed at least partially therein.
8. The polishing article of any of claims 1 to 7, wherein the at least one conductive element extends beyond a plane defined by the surface of the body.
9. The polishing article of claim 8, wherein the at least one conductive element comprises one or more conductive fibers extending beyond a plane defined by the surface of the body, the one or more conductive fibers are in the shape of a coil, one or more loops, one or more strands, an interwoven fabric, or combinations thereof, and the one or more conductive fibers extending beyond a plane defined by the surface of the body are coupled to a conductive base.
10. The polishing article of any of claims 1 to 4, further comprising a biasing member disposed between the at least one conductive element and the body and the biasing member is adapted to urge the conductive element towards the polishing surface to electrically contact the substrate disposed on the polishing surface.
11. The polishing article of any of claims 1 to 10, wherein the body further comprises a connector for connecting the article to a power source.

12. The polishing article of any of claims 1 to 11, wherein the body comprises a polishing portion disposed on a support portion and at least one conductive element is disposed on the conductive polishing portion. 5
13. The polishing article of claim 12, wherein a connector for connecting the article to a power source is disposed between the polishing portion and the support portion and is electrically coupled to the at least one conductive element. 10
14. The polishing article of any of claims 1 to 13, wherein the at least one conductive element comprises a composite of fibers coated with a conductive material, a conductive filler, or combinations thereof, and a binder, and the composite is embedded at least partially in the body. 15
15. The polishing article of claim 14, wherein the binder comprises a polymer based bonding agent selected from the group of an epoxy resin, a silicone, an urethane resin, a polyimide, a polyamide, a fluoropolymer, fluorinated derivatives thereof, or combinations thereof, or the binder comprises a polymeric material selected from the group of polyurethane, polyurethane mixed with fillers, polycarbonate, polyphenylene sulfide (PPS), ethylenepropylenediene-methylene (EPDM) Teflon™ polymers, polystyrene, and combinations thereof. 20 25 30
16. The polishing article of any of claims 1 to 15, wherein the at least one conductive element thereof is coupled to a conductive member disposed in a grooved formed in the body of the polishing article. 35
17. The polishing article of claim 16, wherein the at least one conductive element comprises one or more coiled fibers coated with a conductive material disposed concentrically around the conductive member, an interwoven fabric or fibers coated with a conductive material disposed concentrically around the conductive member, one or more metals, a copper wire or foil disposed on a bar of gold or a metal foil coated with a conductive binder, and combinations thereof. 40 45
18. The polishing article of any of claims 1 to 17, wherein the body comprises a conductive mesh of fibers coated with the conductive material, conductive fillers, or combinations thereof, and a bonding agent disposed thereon. 50
19. A polishing article for processing a substrate comprising: 55
- a body having at least one conductive surface adapted to polish the substrate, wherein the
- conductive surface comprises at least one conductive element comprising conductive fillers, fibers coated with a conductive material, or combinations thereof, disposed in a polymeric material.
20. The polishing article of claim 19, wherein the fiber coated with the conductive material further comprises a nucleation material or a binder material disposed between the fiber and the conductive material.
21. The polishing article of claim 19 or claim 20, wherein the polishing article comprises polyamide fibers with gold disposed thereon and graphite disposed in a polyurethane binder or comprises graphite particles, carbon nanotubes, carbon fibers, and combinations thereof, disposed in polyurethane or silicone.
22. The polishing article of any of claims 19 to 21, wherein the body further comprises a plurality of grooves or perforations formed at least partially therein and a portion of the perforations and a portion of the grooves intersect.
23. The polishing article of any of claims 19 to 22, wherein the body further comprises a connector for connecting the article to a power source.
24. The polishing article of any of claims 19 to 23, wherein the conductive surface has a resistivity of about 50  $\Omega$ -cm or less.
25. The polishing article of any of claims 19 to 24, wherein the polishing article has a hardness of about 100 or less on a Shore D Hardness scale.
26. The polishing article of any of claims 19 to 25, wherein the polishing pad comprises:
- a body having a conductive polishing portion disposed on a support portion, the conductive polishing portion comprising at least one conductive element comprising conductive fillers, fibers coated with a conductive material, or combinations thereof, disposed in a polymeric material and the body comprises a plurality of perforations, the polishing portion comprises a plurality of grooves, and a portion of the perforations and grooves intersect.
27. The polishing article of claim 26, wherein the body further comprises a connector for connecting the article to a power source disposed between the polishing portion and the support portion and is electrically coupled to the at least one conductive element.

28. A polishing article for processing a substrate, comprising:

a body having a surface adapted to polish the substrate and a conductive element comprising a fabric of interwoven fibers coated with a conductive material. 5

29. The polishing article of claim 28, wherein the fabric of interwoven fibers coated with a conductive material comprises a plurality of fibers coated with a conductive material interwoven to form a fabric, a plurality of interwoven fibers to form a fabric that is coated with a conductive material, or combinations thereof. 10 15

30. The polishing article of claim 28 or claim 29, wherein the fabric of interwoven fibers is perforated, woven to form passages, or combinations thereof, for fluid electrolyte flow therethrough. 20

31. The polishing article of any of claims 28 to 30, wherein the body comprises a conductive polishing portion disposed on a support portion, wherein the conductive element comprises the conductive polishing portion. 25

32. The polishing article of any of claims 29 to 31, wherein the conductive surface has a resistivity of about 50  $\Omega$ -cm or less. 30

33. The polishing article of any of claims 28 to 32, wherein the polishing article has a hardness of about 100 or less on a Shore D Hardness scale. 35

34. The polishing article of any of claims 28 to 33, wherein the body further comprises a metal foil disposed on the conductive element.

35. The polishing article of claim 34, wherein the metal foil comprises a plurality of perforations, a plurality of grooves, or combinations thereof. 40
